"Mud Shake" Machine Provides Data for Highway Builders

A typical, unimproved rural road such as thousands of farmers are still forced to depend on in transporting their products to market.

THE contrast between the rutted "mud hole" road at the left and the smooth, hard-surface highway at the right, pictures the whole problem of adequate farm-to-market roads.

Strangely enough the solution of the problem of providing such improved roads to furnish the farmer with proper transportation facilities between farm and market, has been aided by the "mud shake" machine, employed in one of the basic laboratory tests developed in the Arlington, Va., laboratories of the U. S. Bureau of Public Roads. The test provides a method of determining the proportions of sand, clay, silt and other materials in road soils. A first step in this method of soil analysis is to obtain a thorough dispersion of the sample in distilled water by the use of the special "mud shake" machine.

soils have a determining influence upon the service which sand, sand-clay and gravel roads can be ex-

pected to give. The moisture-retaining quality of the soil is among the most important factors. It is the presence of a moisture film between the soil particles that holds them together and provides stability. The extent to which soils develop moisture film cohesion is largely dependent upon the materials of which they are composed.

Increasing use of chemical admixtures such as calcium chloride—a substance which when spread on the road surface slows down evaporation and draws additional moisture from the air—has played an important part in the rapid development of sand, sand-clay and gravel roads that provide a hard, smooth surface, virtually a "soil concrete", at low cost. The road shown at the right, in Onondaga County, N. Y., is a typical example of such calcium chloride treated highways.
