Soggy Biscuits and Indigestion

From time immemorial, leavening gas has made the "touch" which made the paste of flour and water a digestible food—the staff of life. A flat and soggy loaf or biscuit is an unleavened food. So it is that leavening agents such as yeast or baking powder are employed.

To insure to the American housewife complete leavening of her biscuits, cakes, muffins, etc., which is so important to perfect digestion, the pure food authorities found it wise to require a certain standard of leavening strength in baking powder.

To maintain this guaranty of digestibility—to insure minimum deterioration of leavening strength, baking powder is packed in tin. This prevents absorption of atmospheric moisture. Dampness produces premature reaction in the can—results in loss of leavening gas.

The food official, would properly condemn baking powder if packed in cheap sacks.

But what about self rising flour? It comes to the southern housewife from remote northern mills packed in porous bags. What happens to this mixture of baking materials and flour?

Chemical analysis shows that much of it has lost its leavening strength before it reaches the consumer.

Breadstuffs made with such self-rising flours cannot rise properly—they come to the table heavy, flat, and soggy.

Why don't the pure food officials demand that self-rising flours contain 0.5% leavening gas, the equivalent to the 12% required of baking powder?

Calumet Baking Powder is scientifically and legally correct—the last spoonful is as pure and sure as the first.

Packed in tin—keeps the strength in
